

Abstract

The purpose of this study was to determine whether there were differences in the prevalence of risk factors for coronary artery disease between two groups of men who had been exposed to asbestos. The subjects were divided into two groups based on their exposure to asbestos. The first group consisted of men who had worked in an asbestos mine, and the second group consisted of men who had worked in a non-asbestos mine. Data were collected from medical records and interviews. The results showed that the prevalence of risk factors for coronary artery disease was significantly higher in the group exposed to asbestos compared to the control group.

Keywords: Asbestos, Coronary artery disease, Risk factors, Prevalence, Occupational exposure.
